Sezione A-AFFLUSSI METEORICI

TERMINOLOGIA

- Afflusso meteorico (m³) ad un bacino idrografico in un dato intervallo di tempo: volume totale della precipitazione sul bacino in quell'intervallo.
- Altezza di afflusso meteorico (mm) ad un bacino idrografico per un determinato intervallo di tempo: spessore dello strato d'acqua di volume pari all'afflusso meteorico in

quell'intervallo ed uniformemente distribuito sulla superficie del bacino.

3. - Contributo medio di afflusso meteorico (l/s km²) ad un bacino idrografico in un dato intervallo di tempô: quoziente fra afflusso meteorico al bacino nell'intervallo ed il prodotto della durata di questo per l'area del bacino.

CONTENUTO DELLA TABELLA

Riporta, per gli interi bacini imbriferi e per le loro parti più importanti, le altezze di afflusso meteorico mensili ed annue, espresse in mm, ed i corrispondenti contributi medi espressi in l/s km². Per ogni stazione il contributo mensile più elevato è stampato in grassetto e quello più basso in corsivo.

TERMINOLOGIA

1. - Altezza idrometrica (cm): altezza del livello liquido sopra o sotto lo zero dell'idrometro.

 Altezza di massima piena (o magra) in una sezione fornita di idrometro e per un lungo periodo di osservazione: massima o minima altezza idrometrica (m) raggiunta in tutto il periodo di tempo in cui sono state eseguite le osservazioni.

CONTENUTO DELLA TABELLA

La tabella è preceduta dall'elenco e caratteristiche delle stazioni idrometriche che hanno funzionato nell'anno.

TABELLA 1 - Riporta, per alcune stazioni, le altezze idrometriche meridiane rilevate direttamente all'idrometro da parte dell'osservatore oppure dedotte in corrispondenza del mezzogiorno dallo spoglio dei diagrammi per le stazioni fornite di apparecchio registratore.

Al reale bacino di dominio sono stati tolti km 136.40 che competono rispettivamente al bacino imbrifero del Tesa (km 117.22) e del Lago di Santa Croce (km 19.18) le cui acque, in seguito alla costruzione degli impianti idroelettrici del gruppo di Santa Croce, scaricarono nel bacino del Meschio (Livenza).
 Non si tiene conto dei livelli raggiunti dall'ondata di piena causata dalla frana caduta sul Vajont.
 L'altezza di massima piena è stata superata nel novembre dei 1966, ma causa l'asportazione dello strumento non è stato possibile ricavarne il dato.

⁽¹⁾ Le caratteristiche della stazione vennero dedotte dalle pubblicazioni del H.Z. di Vienna. (2) In seguito alla costruzione degli impianti idroelettrici di Pozzolago, il bacino del Lago delle Piazze (km. 2.0), prima appartenente al Bacino del Fersina, viene a far parte del Bacino dell'Avisio. È stata quindi apportata tale variante alla superficie del Fersina e dell'Adige a Trento.

(3) L'altezza di massima piena è stata superata nel novembre del 1966, ma causa l'asportazione dello strumento non è stato possibile ricavarne il dato.

TERMINOLOGIA

- Portata in una sezione e in un dato istante (m³/s): volume di acqua che attraversa la sezione durante l'unità di tempo (minuto secondo) che comprende quell'istante.
- 2. Portata unitaria (o contributo) relativa ad una determinata sezione (l/s km²): rapporto tra la portata nell'unità di tempo (l/s) e l'area del bacino imbrifero sotteso dalla sezione.
- Portata media di una sezione e per un dato intervallo di tempo: rapporto tra il deflusso relativo all'intervallo e la durata di questo.
 - 4. Modulo di una sezione: portata media di un gran numero di anni.
- 5. Portata giornaliera in una sezione e per un determinato giorno: portata media nella sezione in quel giorno.
- 6. Durata di una determinata portata Q in una sezione e relativamente ad un certo intervallo di tempo: numero di giorni di quell'intervallo, nei quali si è verificata una portata non inferiore a Q.
- 7. Portata semipermanente in una sezione e in un dato intervallo di tempo: portata che non è stata superata per metà dei giorni dell'intervallo (ossia di durata uguale a metà dell'intervallo).
- 8. Portata semiannuale di un anno determinato: la portata semipermanente di quell'anno.
- 9. Deflusso in una determinata sezione e per un determinato intervallo di tempo (m³): volume liquido che ha attraversato la sezione nell'intervallo.
- 10. Altezza di deflusso di un bacino idrografico per un determinato intervallo di tempo (mm): spessore dello strato d'acqua di volume pari al deflusso superficiale del bacino in quell'intervallo e uniformemente distribuito sulla superficie del bacino.
- 11. Deflusso giornaliero di una determinata sezione e per un dato giorno (m³): volume liquido che ha attaversato la sezione in quel giorno.
- 12. Deflusso unitario relativo ad una determinata sezione ed in un dato intervallo di tempo (m³/km²): rapporto tra il deflusso dell'intervallo e l'area del bacino imbrifero sotteso dalla sezione.
- 13. Perdita apparente di un bacino idrografico in un determinato intervallo di tempo: differenza tra l'altezza di afflusso meteorico e l'altezza di deflusso relative all'intervallo.
- 14. Coefficiente di deflusso di un bacino idrografico in un determinato intervallo di tempo: rapporto fra l'altezza di deflusso e l'altezza di afflusso meteorico relative all'intervallo.

CONTENUTO DELLE TABELLE

Le tabelle sono precedute da una cartina del Compartimento, corredata di un elenco, ove sono ubicate le stazioni di misura che hanno regolarmente funzionato nell'anno.

Nelle tabelle, per ogni stazione, sono riportati:

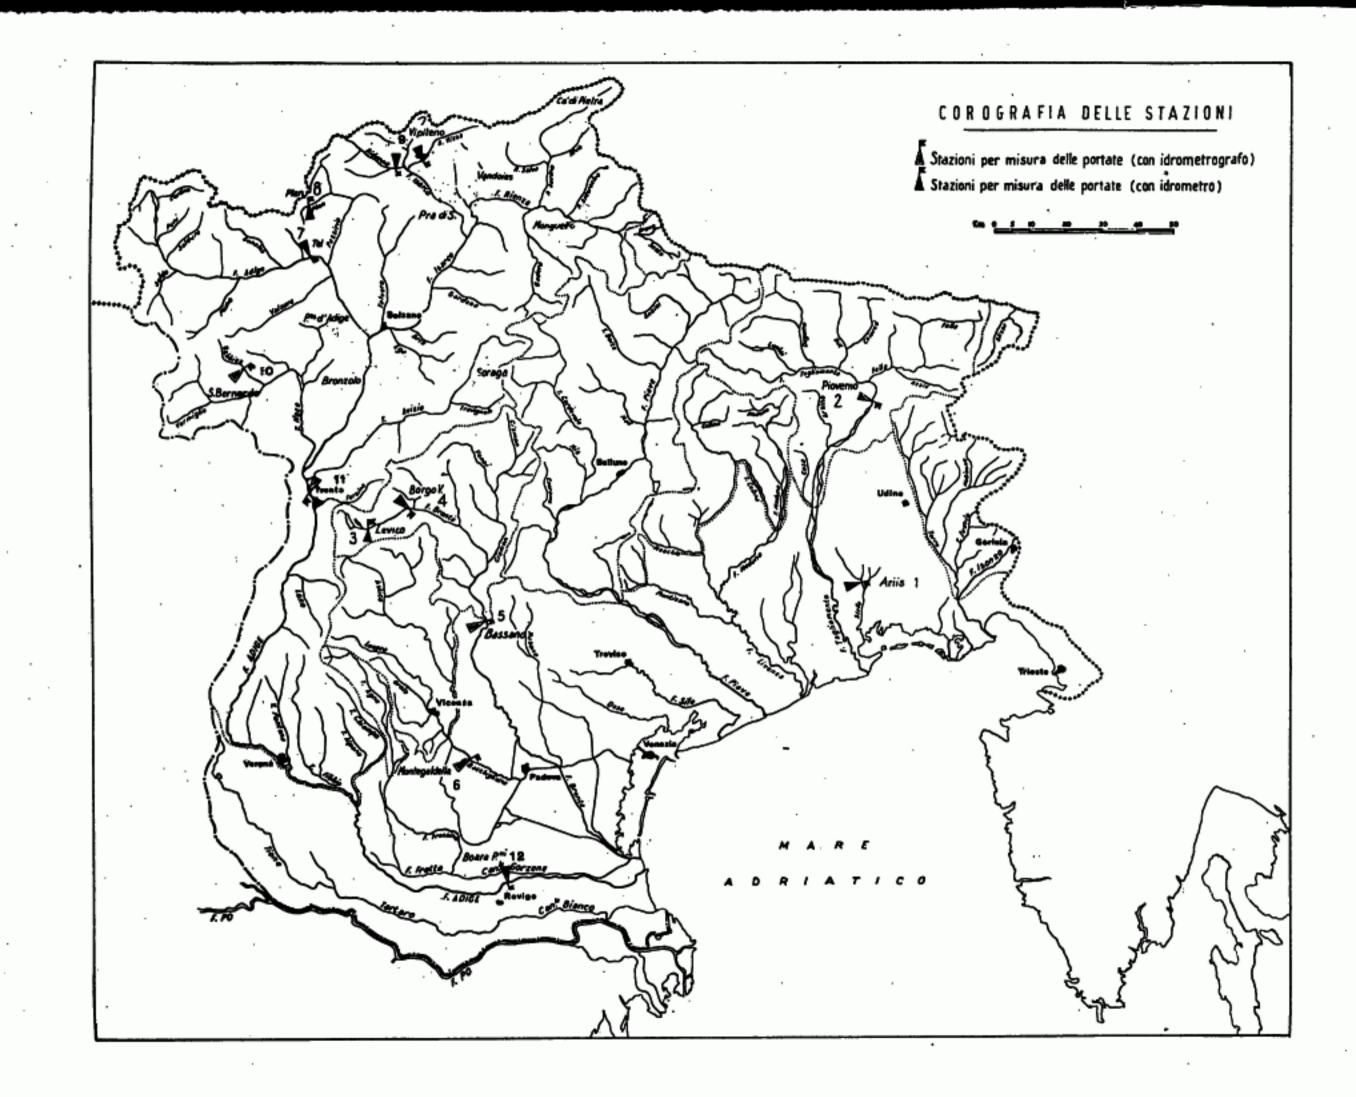

- a) le caratteristiche della stazione e del bacino che alimenta il corso d'acqua relativo, con l'indicazione delle altezze idrometriche e delle portate massime e minime rilevate nel periodo di osservazione;
- b) le portate medie giornaliere espresse in m³/s;
- c) gli elementi caratteristici, mensili ed annui, dell'anno e del precedente periodo di osservazione: le portate, in m³/s, massime, minime e medie giornaliere, i deflussi

- e gli afflussi in mm; i coefficienti di deflusso (rapporto tra i deflussi e i corrispondenti afflussi). I valori calcolati dei coefficienti di deflusso dei mesi primaverili-estivi sono inferiori a quelli reali perché i deflussi, misurati nei vari corsi d'acqua, in corrispondenza delle stazioni di misura, sono influenzati dalle derivazioni ad uso irriguo esistenti a monte delle stazioni stesse;
- d) le portate medie giornaliere corrispondenti a valori caratteristici delle durate espresse in giorni;
- e) la scala numerica delle portate, cioè la traduzione analitica della relazione intercorrente tra le portate e le altezze idrometriche rilevate nella sezione di misura, valide per l'anno cui si riferiscono gli Annali, o per i periodi dello stesso anno, ove specificato.

ELENCO DELLE STAZIONI

- 1. STELLA ad ARIIS
- 2. TAGLIAMENTO a PIOVERNO
- 3. BRENTA a LEVICO
- 4. BRENTA a BORGO VALSUGANA
- 5. BRENTA a BARZIZA (Bassano)
- 6. BACCHIGLIONE a MONTEGALDELLA

- ADIGE a TEL
- PLAN a PLAN
- 9. RIDANNA a VIPITENO
- 10. RABBIES a SAN BERNARDO di RABBI
- 11. ADIGE a TRENTO
- 12. ADIGE a BOARA PISANI

CARATTERISTICHE DELLA STAZIONE: Bacino di dominio: Risorgive; zero idrometrico 7.12 m s.m.; distainza dalla foce km 20 circa; inizio osservazioni marzo 1965; inizio misure marzo 1965. Altezza idrometrica max m 2.03 (4 novembre 1966); minima m 0.40 (13 luglio 1966). Portata max m³/s ». Minima m³/s 23.4 (5-6-7 aprile 1973).

⁽¹⁾ La stazione di misura di Barziza sostituisce quella di Sorson che ha funzionato dal 1922 al 1941. I bilanci calcolati per la sezione di Sorson possono ritenersi validi anche per la stazione di Barziza in considerazione della trascurabile differenza dei bacini sottesi (kmq 4).

CARATTERISTICHE DELLA STAZIONE: Bacino di dominio: 1384 km² (parte permeabile 79%); altitudine max 2341 m s.m.; media 649 m s.m.; zero idrometrico 15.06 m s.m.; distanza dalla foce km 80 circa; inizio osservazioni settembre 1929; inizio misure luglio 1929. Altezza idrometrica max m 8.21 (5 novembre 1966); minima m -0.79 (8 settembre 1962). Portata max m³/s 600 (5 novembre 1966). Minima m³/s 2.61 (8 settembre 1962).

TERMINOLOGIA

Altezza freatimetrica (m): altezza del livello liquido nel pozzo sul livello del mare.

CONTENUTO DELLE TABELLE

Le tabelle sono precedute dall'elenco e caratteristiche delle stazioni freatimetriche che hanno funzionato nell'anno.

TABELLA I - Riporta i valori dei livelli freatrici, riferiti al medio mare, rilevati nei giorni 2, 5, 8, 11, 14, 17, 20, 23, 26 e 29 di ogni mese (eccetto per il mese di febbraio in cui l'ultimo valore si riferisce al giorno 28), ed il valore medio corrispondente.

TABELLA II - Per ognuna delle stazioni considerate nella Tabella I, riporta la quota del piano di campagna ove la stazione è situata ed i valori medi mensili ed annui dei livelli freatici.

Sezione E-TRASPORTO TORBIDO

TERMINOLOGIA

- Portata torbida in una sezione ed in un dato istante: peso del materiale solido in sospensione che attraversa la sezione nell'unità di tempo che comprende quell'istante (kg/s).
- 2. Torbidità specifica in una sezione ed in un dato istante: quoziente fra il valore della portata torbida e quello della portata liquida relativi a quella sezione ed a quell'istante (kg/m^3) .
- Deflusso torbido di una sezione per un dato intervallo di tempo: peso del materiale solido in sospensione che ha attraversato la sezione nell'intervallo (tonn).
- 4. Portata torbida media in una sezione e per un dato intervallo di tempo: quoziente fra il deflusso torbido relativo all'intervallo ed il numero di secondi di questo (kg/s).
- Deflusso torbido unitario in una sezione e per un dato intervallo di tempo: quoziente fra il valore del deflusso torbido relativo a quell'intervallo e l'area del bacino imbrifero sotteso dalla sezione (tonn/km²).

Carta delle stazioni torbiometriche

Elenco delle stazioni

l. - Bassano

II. - Trento

I - BRENTA A BASSANO

CARATTERISTICHE DELLA STAZIONE: a) Bacino di dominio km² 1567 (Bacino utile per le torbide km² 939); parte permeabile 66%; altitudine max 3185 m s.m.; media 1256 m s.m.; distanza dalla foce km 105 circa. Inizio osservazioni torbiometriche: anno 1968. Idrometrografo di riferimento 900 m circa a monte del Ponte Vecchio (sp. d.); quota dello zero idrometrico 105.83 m s.m.Caratteristiche torbiometriche medie annue del periodo 1959 e 1971-72; portata torbida kg/s 1.333, torbidità specifica kg/m³ 0.023, deflusso torbido unitario tonn/km² 44.812.

⁽¹⁾ Sono state eseguite osservazioni torbiometriche anche dal 1932 al 1941. - (2) Il deflusso torbido unitario è calcolato su km 4597 in quanto km 5166 sono sottesi dagli sbarramenti per formazione di serbatoi

MAREOGRAFIA

Nel presente capitolo sono riportati i valori dell'alta e bassa marea osservati durante l'anno nella Stazione Mareografica di PUNTA della SALUTE.

CONTENUTO DELLE TABELLE

Le tabelle riportano i valori di alta e bassa marea registrati nella Stazione e l'orario in cui si sono verificati.

Nelle tabelle, per ciascun mese dell'anno, sono riportati:

- a) per ogni giorno del mese gli orari in cui si sono verificati gli estremi;
- b) i valori degli estremi (alta e bassa marea) espressi in cm;
- c) le medie delle altezze di alta e bassa marea per ciascuna decade;
- d) la media mensile delle altezze di alta e bassa marea.

Le altezze di marea riportate nelle tabelle sono riferite allo zero mareografico di PUNTA della SALUTE (corrispondente, nel 1897, al piano fondamentale della rete altimetrica dello Stato).

Tale livello di riferimento si trova attualmente ad una quota inferiore di circa 23 cm al livello medio marino attuale.

Sono stampati in grassetto ed in corsivo rispettivamente i valori massimi ed i valori minimi.

CARATTERI IDROLOGICI DELL'ANNO 1973

Lo scopo del presente capitolo è quello di mettere in evidenza le caratteristiche idrologiche e climatiche dell'anno 1973 confrontando i valori rilevati negli Osservatori meteorologici di Trieste, Venezia - Lido, Padova e Sadocca, ed in alcune Stazioni termopluviometriche, idrometriche e di misura delle portate, opportunamente scelte nel Compartimento, con i rispettivi valori medi di un lungo periodo di osservazioni ("valori normali").

I. - TEMPERATURA

Una prima lettura della Tab. I indica che l'anno 1973, per quanto riguarda le temperature medie mensili, non si è scostato sensibilmente dalle medie del periodo.

L'analisi delle medie mensili conferma l'andamento regolare delle temperature nell'anno 1973.

Il mese più caldo è stato agosto in tutte le stazioni tranne che a Sadocca (in cui è stato luglio, come nella media del periodo), quello più freddo è stato dicembre, tranne che a Trieste (in cui è stato gennaio, come nella media del periodo).

Rispetto alle medie mensili del periodo, quelle mensili del 1973 presentano le seguenti variazioni:

- gennaio e agosto sono stati più caldi in tutte le stazioni;
- novembre e dicembre sono stati più freddi in tutte le stazioni;
- febbraio è stato più caldo in tutte le stazioni tranne che a Rovigo (in cui è stato uguale alla media del periodo);
- ottobre è stato più freddo in tutte le stazionitranne che a Trieste;
- maggio, giugno e settembre sono stati più caldi in tutte le stazioni tranne che a Rovigo (maggio), Udine (giugno e settembre), Sadocca (maggio);

Comunque le variazioni dalla media si sono sempre mantenute entro piccoli ordini di grandezza.

La Tabella II mette in evidenza i valori medi e assoluti stagionali.

L'inverno si è manifestato ovunque più caldo rispetto alla media tranne che a Udine.

Anche l'estate è stata ovunque più calda tranne che a Trieste e a Udine. L'autunno è stato invece sempre più freddo rispetto alla media, tranne che a Vicenza, mentre la primavera è stata più fredda tranne che a Belluno, Vicenza e Trento.

II. - PRESSIONE ATMOSFERICA

L'esame della Tabella III, che riporta i valori mensili medi ed assoluti della pressione nell'anno 1973 e nel periodo 1914-1972 registrati nell'osservatorio di Venezia-Lido, pone in evidenza che la pressione media è stata maggiore della pressione media del periodo, salvo nei mesi di febbraio, aprile e luglio; che lo scostamento positivo massimo è stato in marzo e quello negativo in febbraio; che l'escursione massima si è avuta in dicembre e infine che l'escursione nei singoli mesi è stata inferiore alla media, salvo nei mesi di febbraio, luglio, ottobre e dicembre.

III. - VENTO

Come viene indicato dalla Tab. IV, l'anno 1973 è stato meno ventoso nei quattro Osservatori considerati, lo è stato mediamente nelle Stazioni di Padova, Sadocca e Venezia - per quest'ultima lo si piò tranquillamente affermare nonostante la mancanza di alcuni dati - mentre lo è stato sempre a Trieste.

L'analisi delle Tab. V e VI è più indicativa in quanto risulta che nei mesi di aprile e giugno a Venezia-Lido la velocità del vento ha raggiunto punte massime rispettivamente di 83 km/h e 76 km/h che risultano comunque inferiori a quelle massime del periodo.

A Padova e a Trieste la velocità massima annua del vento è stata toccata a marzo.

IV. - NEBULOSITÀ

La Tab. VII indica che la nebulosità nell'anno 1973 ha oscillato intorno alla media del periodo in tutti gli osservatori.

| | | | | | | | | | | | | | | |

Come è naturale, i mesi estivi sono stati più sereni, mentre quelli invernali sono stati più coperti con un massimo di 7/10 di cielo coperto in aprile a Venezia.

V. - UMIDITÀ RELATIVA

La Tab. VIII indica che l'anno 1973 è stato meno umido del normale in tutti e quattro gli osservatori.

Ovviamente i mesi più umidi sono stati quelli invernali e quelli meno umidi quelli estivi. Trieste ha confermato di essere città meno umida rispetto a Venezia, Padova e Sadocca.

A questo punto si può dire che tutte le tabelle analizzate finora confermano che l'anno 1973 si è adeguato alla normalità del periodo.

Basta osservare la Tab. I e la Tab. VIII per rendersi conto che gli eventi atmosferici e le temperature dell'aria non hanno avuto alcun carattere originale rispetto alla normalità.

VI. - PRECIPITAZIONI

La Tab. IX fornisce la distribuzione degli afflussi meteorici durante l'anno in determinate stazioni del Compartimento.

Tutte le stazioni prese in esame in detta Tabella evidenziano per il totale annuo un rapporto inferiore alla media del periodo (tranne che a Pejo in cui è 1,03, con minimo a Portogruaro 0,74).

Il mese più piovoso è stato settembre, salvo a Forni Avoltri (aprile), S. Martino di Castrozza, Silandro (agosto), Longega, Pejo e Denno (luglio).

I mesi di gennaio e febbraio sono stati invece i meno piovosi a seconda delle zone.

La Tab. IX non riporta risultanze conclusive; ogni stazione ha un proprio andamento particolare, ma in generale si può affermare che la distribuzione delle precipitazioni dell'anno 1973 sia stata regolare.

Tali precipitazioni, come di consueto, si sono quasi ovunque concentrate nelle stagioni primavera - estate (vedi Tab. X).

Tabella X - Precipitazioni stagionali (espresse in percentuale del totale annuo)

| Trento | 944 | 15.0 | 28.1 | 28.2 | 28.7 | 13.3 | 14.7 | 36.8 | 35.2 | 840 | 0.89 |
| Padova | 862 | 21.5 | 28.9 | 21.8 | 27.8 | 31.0 | 13.5 | 23.1 | 32.4 | 744 | 0.81 |

Ciò viene ulteriormente confermato anche dai grafici delle Fig. 1a-i; tuttavia tale riscontro non consente di verificare una certa regolarità distributiva nei bacini.

Un orientamento chiarificatore lo si può desumere dalla Tab. XI che indica, in prima approssimazione, che la condizione più significativa dell'aumento degli afflussi meteorici è da attribuirsi ai bacini del Tagliamento e del Brenta, mentre invece una leggera diminuzione la si riscontra nei bacini del Piave, del Bacchiglione, dell'Agno-Guà e dell'Adige.

Le Tabb. XI e XII rappresentano le quantità massime di precipitazione in periodi di più ore e più giorni consecutivi.

VII. - IDROMETRIA

Come risulta dalla Tab. XIV, il 1973 è stato un anno relativamente tranquillo durante il quale non si sono verificati eventi da considerarsi eccezionali.

Si può rilevare infatti che le altezze idrometriche (vedi sezione "Idrometria" Tab. I) registrate nelle stazioni del Compartimento risultano comprese tra le massime e le minime del periodo.

Le uniche eccezioni sono rappresentate da Stella ad Ariis, Sile a Trepalade, Adige a Legnano e Badia Polesine che nel 1973 hanno presentato minime altezze idrometriche inferiori alle minime del periodo precedente.

VIII. - PORTATE E BILANCI IDROLOGICI

Pur considerando che i valori delle portate, soprattutto di quelle minime, sono state alterate da operazioni di invaso e svaso di serbatoi a monte per usi idroelettrici e, per i corsi d'acqua principali, anche da derivazioni per usi diversi e promiscui spesso senza restituzione, si può affermare che la scarsità del regime idrico nei corsi d'acqua compresi nel Compartimento per il 1973, come risulta anche dalla Tab. XV, conferma i dati precedentemente presentati.

Il mese più "ricco" d'acqua nell'anno 1973 è stato ottobre.

In definitiva, entro i limiti della presente trattazione e a conclusione di questa breve analisi, si può asserire che l'andamento stagionale dell'anno 1973 rientra nella normalità pur con le alternanze climatologiche che fanno contraddistinguere i vari periodi che si susseguono, caratterizzandone, in maniera più o meno significativa, le risultanze dei fenomeni metereologici.
